

RECAP & PATH FORWARD

MaiaEdge for HGC International Business

Turn HGC's reach into private fabric you sell.

Following our conversation at ITW. Prepared for Cliff Tam and the HGC International team. June 2026.

Private paths. Any network. Instantly.

CARRIER INFRASTRUCTURE FOR FEDERATED PRIVATE NETWORKING

The short version

HGC has already turned connectivity into a product, from the SDN marketplace and on-demand multi-cloud to the DCI clusters now live across Hong Kong, Singapore, Malaysia, the Philippines, and Thailand. The piece still ahead is the east-west reach AI is pulling forward, dynamic data-center-to-data-center and cloud-to-cloud paths across your own footprint and the carriers you partner with, sold under your brand. MaiaEdge is carrier infrastructure you rack inside your own network to do exactly that, on a private Ethernet layer that sits alongside the IP and peering you already run.

What we heard

- Infrastructure-first: subsea and terrestrial cable, your own data centers, internet exchanges running both IP and Ethernet peering, and DCI clusters across the major Asian hubs.
- AI is the throughline: an AI-focused data center in Asia, GPU as a service with your GPU cloud partners, and the East-West Gateway in Johor tying submarine landings, terrestrial fiber, DCI, and internet exchange into one corridor.
- You have productized connectivity already, and you want to add services without more operational complexity.
- Your questions were the right ones: how this sits with the IP and peering layer you run, and whether it stays standards-based and multivendor.

Why moving now beats waiting

The reach AI workloads need is east-west, data center to data center and cloud to cloud, across operators. It is the half that on-net automation and a third-party fabric cannot cover on their own, because the on-demand experience stops where your own footprint or that fabric's footprint stops. As the Johor corridor and the Philippine DCI fill up, the customers riding them will expect to provision and watch their paths the way they do in the cloud, including in metros where you have no fabric rack today.

One shift sharpens the timing. The third-party fabric layer operators lean on for on-demand reach is moving into compute and AI services, against the same customers carriers serve. Owning that layer inside your own network is how the reach compounds for HGC, not for someone in the middle.

The use cases we mapped

USE CASE	WHAT IT DOES	THE PAYOFF FOR HGC	WHO IT HELPS
Dynamic interconnect from your own data centers	A 1RU device in your meet-me rooms turns static cross-connects into programmable Ethernet. One customer port carries separate paths to Bangkok, Singapore, or a Tokyo cloud region, each on its own tag.	New interconnection revenue from the data centers and DCI you already run, reaching metros where no third-party fabric has a rack. Your portal, your rate card.	Wholesale, data center ops

USE CASE	WHAT IT DOES	THE PAYOFF FOR HGC	WHO IT HELPS
Federate with carriers, harden subsea on the path layer	Bring up an interconnect with another carrier in minutes over DIA or a wave, not a 60-90 day build. Put each subsea cable on its own private Ethernet path, so load balancing and failover happen on the path layer, not in complex MPLS.	Long-cycle subsea and private-line capacity becomes instantly activatable paths, and you reach partners you cannot reach today without a build. Hop-by-hop visibility you keep, even on legs you do not own.	Wholesale, carrier relations, network engineering
Be the on-ramp and gateway for the AI corridor	Deliver cloud on-ramp from any site under your brand, with the public fabrics only as backend, and stand up a gateway to the neoclouds your GPU customers want, with a branded portal that pulls AWS and Azure telemetry end to end.	The AI story for Johor and the Philippines, finished with SLA-backed paths and the proof every customer asks for. Cloud connectivity that gets more profitable as it scales.	Wholesale, OTT and AI product, customer SLA

05 OPEN QUESTIONS

Working through the open questions

"How do we run this without giving up our Layer 3, when we operate the exchange with IP and Ethernet peering?" The goal is to add dynamic private paths without disturbing the peering your customers depend on. MaiaEdge is Ethernet in, Ethernet out. It sits alongside your IP and peering layer rather than in place of it, so BGP and your exchange stay exactly as they are. When you want the same peering to appear in two metros, a device at each end bridges it, with no separate Layer 2 build between them.

"Is it standards-based, and will it work with our other vendors?" It has to drop into a multivendor Ethernet environment without a forklift. It speaks standard Ethernet and Q-in-Q, so whatever you hand it, IP or MPLS, passes through untouched. Encryption is standard AES-256 at line rate, and it complements the routers and optics you already run rather than replacing them.

06 PROOF

What operators like you have seen

IENTC, the carrier we mentioned at ITW, runs more than 800 cell sites into 20-plus data centers on MaiaEdge and is putting a device in its core so other carriers peer with it in minutes, in its CEO's words, "very, very simple." A carrier with five geodiverse subsea cables replaced complicated MPLS load balancing with private Ethernet paths and said its circuits had never worked so well.

The team behind MaiaEdge built and sold Acme Packet to Oracle and 128 Technology to Juniper. This is its third networking category, and the reason the device does the hard part instead of your team.
